

1

1. False. When the graph is a spanning tree, every edge is used.
2. False. We need a reduction from 3-SAT to X.
3. The minimum capacity of a cut = the maximum possible flow.
4. False. See Quiz 5 Q8.
5. The output of X is always at most  $3 \cdot \text{OPT}$  where OPT is the optimal value of the minimization problem.
6.  $|V| - k$ .

- (a) We follow the DFS tree, except that we go over and then back in every subtree from a back-edge.
- (b) We visit nodes in any topological order. When we visit a node  $u$ , its parents and other ancestors must have been visited and their distances have been found. So we set

<https://powcoder.com>

$$\text{dist}(u) = \min_{v \in \text{par}(u)} \text{dist}(v) + d(u, v)$$

Let  $\text{OPT}(k, i)$  be the minimum maximum weights if we hold the first  $i$  books using  $k$  shelves. The final answer is  $\text{OPT}(K, n)$ . Base:  $\text{OPT}(k > 0, 0) = 0$  and  $\text{OPT}(0, i \geq 1) = +\infty$ . Recurrence:

$$\text{OPT}(k, i) = \min_{1 \leq j \leq i} \left\{ \max \left\{ \text{OPT}(k-1, j-1), \sum_{p=j}^i w_p \right\} \right\}$$

Running time: there are  $O(nk)$  subproblems, each taking  $O(n)$  time, so the overall running time is  $O(n^2k)$ .

4

Let  $\text{OPT}(j)$  be the maximum score we can get from the first  $j$  rows and columns (position on the diagonal). Base case:  $\text{OPT}(0) = 0$ , and recurrence:

$$\text{OPT}(j) = \max_{i: 1 \leq i < j} \{ -\alpha + f(B[i \dots j]) + \text{OPT}(i) \}$$

The final answer is  $\text{OPT}(n)$ .

Runtime is  $O(n^2)$  if we assume every call to  $f$  takes constant time.

## 5

We show  $\text{INDEPENDENT SET} \leq_P \text{HYPER-COMMUNITY}$ . For a  $\text{INDEPENDENT SET}$  instance with graph  $G = (V, E)$  and parameter  $k$ , we create a  $\text{HYPER-COMMUNITY}$  instance  $(G' = (V, E'), k)$  by inverting the edge set, that is, an edge is in  $E'$  if and only if it is not in  $E$ . Since the graph in  $\text{HYPER-COMMUNITY}$  is directed, we replace every undirected edge in  $E'$  with two directed edges with opposite directions. In this way,  $U \subseteq V$  is an independent set if and only if  $U$  is a hyper community in  $G'$ .

## 6

We show  $\text{HAMILTONIAN CYCLE} \leq_P \text{REQUIRED PATHS SUBGRAPH}$ .

*Reduction:* Assume the Hamiltonian Cycle instance is  $G = (V, E)$ . We set  $R_{ij} = 2$  for any two different vertices and set  $R_{ii} = 0$  for any vertex. And we set  $b = |V|$ .

*Correctness:* If there is a Hamiltonian Cycle, this cycle contains exactly  $b$  edges and the set of these edges is a feasible solution to the  $\text{REQUIRED PATHS SUBGRAPH}$  instance, because every pair of vertices are in a cycle. Conversely, assume a set of  $b$  or fewer edges satisfies the constraints of the  $\text{REQUIRED PATHS SUBGRAPH}$  instance. This means every pair of vertices are connected and are in a cycle, indicating the set has exactly  $b$  edges. (Otherwise, the graph is a tree with no cycle, or is not a connected component.) This further implies there is exactly one cycle which contains all vertices because there is exactly one cycle. Hence, the  $b$  edges form a Hamiltonian cycle.

## 7

The  $k$  persons in  $P$  for different persons in  $D$  are disjoint. In the graph, we have a super-source  $s$ , a super-sink  $t$ , one node  $d_i$  for the  $i$ th person in  $D$ , one node  $p_i$  for the  $i$ th person in  $P$ , and two auxiliary sinks  $t^+, t^-$  controlling the number of smokers. About edges:

1.  $s$  is connected to every  $d_i$  with capacity  $k$
2.  $d_i$  is connected to  $p_j$  iff the two persons share at least  $m$  mutations, and the capacity is one if connected
3.  $p_j$  is connected to  $t^+$  if he's a smoker, and to  $t^-$  otherwise, with capacity 1 in either case
4.  $t^+$  and  $t^-$  are connected to  $t$  with capacities  $k|D|/3$  and  $+\infty$ , respectively

We select  $p_j$  if and only if a flow passes  $p_j$ .

## 8

We show two possible reductions, one from  $\text{SET COVER}$  and another from  $\text{VERTEX COVER}$ .

**Possible solution #1:** We show  $\text{SET COVER} \leq_P \text{DOMINATING SET}$ .

*Reduction:* For  $\text{SET COVER}$  instance  $(U, \{S_i\}_i, k)$ , we create a graph  $G = (V, E)$ . We create a node  $s_i$  for each set  $S_i$  and a node  $u_i$  for each element in  $U$ . We connect nodes  $s_i$  and  $u_j$  by an edge with capacity if the  $j$ th

element in  $U$  is in  $S_i$ . In addition, we create an extra  $s$  node that is connected to any other  $s$  nodes but not to any  $u$  nodes. We also connect every pair of  $s$  nodes. And the DOMINATING SET instance is  $(G, k)$ .

*Correctness:* We first show, if the SET COVER instance has answer yes, then the answer to the DOMINATING SET is also yes. To show this, we construct a subset of nodes by select node  $s_i$  iff set  $S_i$  is selected.

Conversely, we must have selected some  $s$  nodes in order to cover the extra  $s$  node. If we selected a  $u$  node, we replace it with any  $s$  nodes to which it connects. After a series of transformations, all nodes are covered and the total number of nodes doesn't increase. So the corresponding set of subsets is a valid set cover.

**Possible solution #2 (sketch):** We reduce Vertex Cover (VC) to DS to show that it is NP-complete. Given an instance of VC, with graph  $G = (V, E)$  and parameter  $k$ , construct a new graph  $G'$ . First add all vertices and edges of  $G$  to  $G'$ . Then for each edge  $e(u, v) \in E$ , add a node  $w$  to  $V'$  and add edge  $(u, w)$  and  $(v, w)$  to  $E'$ .
